2/4TXCB036AC3HCAA  2/4TXCC049AC3HCAA

ALL phases of this installation must comply with NATIONAL, STATE AND LOCAL CODES

IMPORTANT — This Document is customer property and is to remain with this unit. Please return to service information pack upon completion of work.

A. GENERAL

These coils are designed for use in combination with a heat pump or cooling outdoor section using R-22 (2TXC) or R-410A (4TXC) REFRIGERANT. These coils may be converted for use with a horizontal furnace as well.

The 2/4TXC equipment has been evaluated in accordance with the Code of Federal Regulations, Chapter XX, Part 3280 or the equivalent. “Suitable for Mobile Home use” The height of the Furnace, Coil and discharge duct work must be 7 ft. or less.

Inspect the coil for shipping damaged. Notify the transportation company immediately if the coil is damaged.

B. APPLICATION INFORMATION

1. FURNACE AND COIL

The coil MUST BE installed downstream (in the outlet air) of the furnace.

These coils fit the 14½" , 17½" , 21" , 24½" width furnaces without any adapters in vertical upflow, downflow, or horizontal application.

2. INDOOR UNIT AIRFLOW

Indoor unit must provide the required airflow for the heat pump or cooling combinations approved for these coils.

IMPORTANT: Review your installation requirements. Check the table on the outline drawings and note all dimensions for your coil before beginning the installation.

C. RECOMMENDATION

If a coil is part of the total system installation, use the Installer's Guide packaged with the furnaces, and outdoor sections, and thermostat for physically installing those components.

D. INSTALLING THE COILS

1. UPFLOW GAS FURNACE - 2/4TXC

   a. Be sure the furnace is turned off and the flue pipe is removed if it is in the way.
Standoffs and screws (See Figure 2) are included with the cased coils for attachment to the furnace. There are clearance alignment holes near the bottom of the coil wrapper. Drill screws are used to engage the top flanges of the furnace. The standoff is inserted into the cabinet alignment hole (See Figure 3). The drill screws are inserted through the standoffs then screwed into the furnace top flange. The coil is always placed downstream of the furnace airflow. The above instructions apply if the coil is on top of an upflow furnace. The coil and furnace must be fully supported when used in the horizontal. The standoffs and screws are strictly for securing alignment, not for support in horizontal.

3. DOWNFLOW GAS FURNACE
When a coil is used with a downflow furnace, a subbase is not required between the coil case and combustible flooring.

a. Place the coil case on the furnace supply air plenum.
b. Secure the coil case to the plenum.
c. Set the furnace on top of the coil case, making sure that the back side of the discharge opening is snug up against the duct flange at the top rear of the coil case.
d. Secure the coil case to the furnace.

4. DOWNFLOW GAS FURNACE -- Add On Cooling
a. Turn the furnace power OFF, remove the flue pipe, and disconnect the fuel and power lines.
b. Raise the furnace to provide sufficient clearance to mount the coil case beneath it. Modifications will be required to the existing return air ductwork to permit the furnace to be raised.
c. Place the coil case on the furnace supply air plenum.
d. Secure the coil case to the plenum.
e. Set the furnace on top of the coil case, making sure that the back side of the discharge opening is snug up against the duct flange at the top rear of the coil case.
f. Reconnect the flue pipe and the fuel and power lines.

E. FURNACE IN HORIZONTAL POSITION - 2/4TXC
The noncondensing forty inch (40") height furnaces may be laid on either side for horizontal application. The forty inch (40") height condensing downflow/horizontal and upflow/horizontal furnaces may only be rotated onto their left side. The connection brackets for horizontal coil use are included with the downflow furnaces. (See Figures 4 and 5)

Caution: Both the coil and furnace must be fully supported. Do not attempt to suspend the coil using the brackets.

a. The 2/4TXC coil case is rotated so the apex of the coil is away from the furnace and the auxiliary drain pan is now on the lower side.
IMPORTANT:
The 2/4TXC cased coil must be placed downstream of the furnace, with the apex of the coil always pointing in the direction of the airflow for horizontal installation. The 2/4TXC cased coil may be installed with upflow or downflow furnace models that provide horizontal right airflow applications. However, the coil must be rotated 180 degrees placing the coil service access opposite the furnace service access. See Figure 6.

b. The base of the coil enclosure is placed flush against the downflow/horizontal furnace. Upflow/horizontal condensing furnaces have the coil match the top flange.

c. There are three brackets included with the furnace which are used to connect the furnace and coil together. See Figure 4.

The connection will use two existing screws on the coil enclosure (one on each of the sides at the bottom) and the remaining screws needed are included with the brackets.

d. Two rear brackets are used and one front bracket. Each of the rear side brackets will be attached by two additional screws. One in the coil enclosure and one in the furnace. See Figure 5.

e. The front bracket is positioned with the narrow edge against the coil enclosure and the wide edge against the furnace. Two screws each are driven into the coil enclosure and furnace.

f. There is a splash guard packaged with the coil. This guard is for horizontal coil installation only. The guard has a bend which is inserted into the front channel of the horizontal drain pan on the outlet air side of the coil case. The guard is then rotated downward until it rests in the drain pan. One sheet metal screw is driven through the coil case duct flange on the front side and into the splash guard side hole. See Figure 7.

F. INSTALLING REFRIGERANT LINES
The following steps are to be considered when installing the refrigerant lines:

a. Determine the most practical way to run the lines.

b. Consider types of bends to be made and space limitations. NOTE: Large diameter tubing sizes will be difficult to rebend once it has been shaped.

c. Determine the best starting point for routing the refrigerant tubing --INSIDE OR OUTSIDE THE STRUCTURE.

d. Provide a pull through hole of sufficient size to allow both liquid and gas lines to clear. The location of this hole (if practical) should be just above the wall plate which is resting on the foundation.

e. Be sure the roll of tubing is of sufficient length.

f. Uncoil the tubing - do not kink or dent. If the line set is prefabricated with fittings, the Quick-Attach fittings with the pressure tap always connects to the outdoor unit, and the indoor fittings must be removed.

g. Route the tubing making all required bends and properly secure the tubing before making final connections.

NOTE: These lines must be isolated from the structure and the holes must be sealed weather tight after installation.

G. FIELD FABRICATED INTERCONNECTING LINES

a. The following procedure should be used for connecting tubing to the coil or the Outdoor Unit.

b. More information concerning the installation of refrigerant lines is covered in the Installers Guide packaged with the outdoor unit. Evacuation, leak testing and brazing procedures are included in those instructions before starting the installation of refrigerant lines.
There is only a holding charge of dry air in the indoor coil, therefore no loss of operating refrigerant charge occurs when the sealing plugs are removed.

Note:
TXV bulb MUST be protected (wrapped with wet rag) or removed, while brazing the tubing. Overheating of the sensing bulb will affect the functional characteristics and performance of the comfort coil.

1. Remove both seals from the indoor coil. The braze caps are soft soldered.
2. Field supplied tubing should be cut square, round and free of burrs at the connecting end. Clean the tubing to prevent contaminants from entering the system.
3. Run the refrigerant tubing into the stub tube sockets of the indoor unit coil.
4. Braze and evacuate according to indoor and outdoor installation instructions.
5. Flow a small amount of nitrogen through the tubing while brazing.
6. Use good brazing technique to make leakproof joints.
7. Minimize the use of sharp 90° bends.
8. Insulate the suction line and its fittings.
9. Do NOT allow un-insulated lines to come into contact with each other.

**CAUTION:** Do not open refrigerant valve at the outdoor unit until the refrigerant lines and coil have been brazed, evacuated, and leak checked. This would cause contamination of the refrigerant or possible discharge of refrigerant to the atmosphere.

I. LEAK CHECK
1. Using a manifold gauge, connect an external supply of dry nitrogen to the gauge port on the liquid line.
2. Pressurize the connecting lines and indoor coil to 150 PSIG maximum.
3. Leak check brazed line connections using soap bubbles. Repair leaks (if any) after relieving pressure after relieving pressure.
4. Evacuate and charge the system per the instructions packaged with the outdoor unit.

J. CONDENSATE DRAIN PIPING
Condensate drain connections are located in the drain pan at the bottom of the coil/enclosure assembly. The female threaded fitting protrudes outside of the enclosure for external connection.
1. The drain hole in the drain pan must be cleared of all insulation.
2. Insulate the drain line to prevent sweating and dripping. It is always recommended that an auxiliary drain pan be installed under a horizontally installed evaporator coil or 90% gas furnace. Connect the auxiliary drain line to a separate drain line (no trap is needed in this line).
I. CLEANING THE COIL

The two piece door (3-piece on 24.5” wide models) allows removal of the outer casing doors without interference from refrigerant or condensate lines. Once the outer doors are removed the split inner coil panels can be easily removed. The inside and outside of the coil can be easily cleaned with a brush and vacuum with the panels removed. See Figure 10.

The foil covered insulation on 2/4TXC coils should be wiped down and residual dirt and dust should be vacuumed up to maintain good air quality. See Figure 11.
